

Lab-6 (AI & ML Lab)

1. Write Python code to get the total number of elements in the DataFrame.
2. Write Python code to find the memory usage of each column in bytes.
3. Write Python code to display the first 5 rows of the DataFrame using the head () function.
4. Write Python code to display the last 5 rows of the DataFrame using the tail () function.
5. Write Python code to access a scalar value using the .at method.
6. Write Python code to access a scalar value using the .iat method.
7. Write Python code to select rows and columns by label using .loc [].
8. Write Python code to display the data types of each column using .dtypes.
9. Write Python code to select object (categorical) columns from the DataFrame.
10. Write Python code to exclude object type columns from the DataFrame.
11. Write Python code to perform statistical analysis of the dataset using describe ().
12. Write Python code to calculate the standard deviation and variance of a column.
13. Write Python code to count the number of missing values in each column.
14. Write Python code to select rows where Age is greater than 30.
15. Write Python code to drop unnecessary columns from the dataset.
